

How do photovoltaic inverters start-up?

Provided by the Springer Nature SharedIt content-sharing initiative Starting-up of photovoltaic (PV) inverters involves pre-charging of the input dc bus capacitance. Ideally, direct pre-charging of this capacitance from the

What affects the start-up transient of PV modules?

The start-up transient is also affected by the contactor connecting the PV modules to the inverter input dc bus. In this work, the start-up current and voltages are measured experimentally for different parallel and series connections of the PV modules.

Can a PV Grid-connected inverter reduce pollution?

As the core of the whole photovoltaic system, PV grid-connected inverter can be able to promote the quality and velocity of production electricity (Fan et al. 2018; Yilmaz et al. 2019; Cheng et al. 2014), which can cut back the THD of the incoming current and reduce the pollution to public power grid (Hassaine et al. 2014; Xu et al. 2014).

Is direct pre-charging of PV module capacitance possible?

Ideally, direct pre-charging of this capacitance from the PV modules is possible as the PV modules are current limited. Practically, the parasitic elements of the system such as the PV module capacitance, effective wire inductance and resistance determine the start-up transient.

How does a PV array dynamic model work?

PV array dynamic model, connected to the dc bus of an inverter, via a connecting cable, including contactor resistance. In the analysis presented earlier, the connecting cable was modelled by a series impedance of resistance and inductance, similar to a short transmission line, and the cable capacitance was ignored.

What is PV module impedance?

In the present work, the PV module impedance is evaluated from the perspective of evaluating the pre-charge current that can occur in a PV array when an inverter dc bus is connected. For this, the experimentally obtained current response is analysed as a simplified second-order model.
