Where do wind turbine sensors record temperature?

Usually sensors record the temperature of at least three locations in the gearbox. Sensor locations include driven-end (DE) bearing, Non-driven-end (NDE) bearing and oil sump temperature. Generator - generator bearings can also constrain wind turbine output.

Can a 2 MW wind turbine generator be thermally analyzed?

This paper focuses on the thermal analysis of a 2 MW wind turbine generator. The goal is to estimate the stator winding temperature with a model as straightforward as possible. Boundary conditions are that no additional sensor than the ones already installed in the wind turbine should be used.

How can condition monitoring help a wind turbine?

It is demonstrated that the technique can identify dangerous generator over temperature before damage has occurred that results in complete shutdown of the turbine. Condition monitoring can greatly reduce the maintenance cost for a wind turbine.

Do wind turbines need additional sensors?

Boundary conditions are that no additional sensor than the ones already installed in the wind turbine should be used. In this paper, a thermal model for the temperature analysis is presented as well as a sensitivity analysis of the model parameters.

How do you calculate a generator temperature variation curve?

To obtain the generator temperature variation curve,  $R_{th} = 1/25 \text{ K/W}$ ,  $C_{th} = 4,000 \text{ Ws/K}$ , ambient temperature  $\theta_{amb}(t) = 20 \text{ }^\circ\text{C}$  are assumed in the model. The initial winding temperature is set as  $0 \text{ }^\circ\text{C}$  and the simulation period is for 1,400 s. ...

How do generator bearings affect wind turbine output?

Generator - generator bearings can also constrain wind turbine output. Typically, the wind turbine SCADA system will record the driven end and non-driven end (referred to as DE and NDE). In addition to generator bearings, the SCADA system also records the stator winding temperature.
